Agent mandates across organisational boundaries

A mandate an AI agent carries itself, verifiable by another organisation.

Michael Owen Meijer, Oomny B.V. · senior identity architect and AI engineer for government and cloud

The problem

An AI agent working for a municipality needs data from another organisation, for example an income register. That organisation does not know the agent and has no account for it. Yet it must be certain which organisation the agent acts for, for which purpose and which case, and that the mandate still holds right now. An account per agent at every party, or a call back to the municipality on every request, makes the chain cumbersome and brittle.

The approach

The municipality issues the mandate as a verifiable credential. The agent carries it itself:

- **The mandate as a credential.** An employee consents and the municipality signs an SD-JWT VC (built on RFC 9901) with the purpose, the allowed actions and the case files. The mandate is bound to the agent's key and valid for one hour at most.
- **Only what is needed.** On every call the agent discloses only the purpose, that one action and that one case file. Who the employee is stays hidden. A key-binding JWT over a single-use nonce from the register makes a stolen credential without the agent's key, or a replayed presentation, worthless.
- **Verification without an account.** The register verifies with its own trust list and the municipality's public signing keys and status list. It has no account at the municipality and does not call back on every request.
- **Revocable.** The municipality revokes the mandate through a Token Status List. If the municipality is reachable, the register refuses the agent within five seconds of revocation in the demo; during an outage it uses its cached status list at most until the status token expires. A kill switch blocks the agent's key.
- **Audit trail on both sides.** Municipality and register each keep a hash chain: issuance, revocation, kill switch, every admission and every refusal.

The evidence

A public repository with a working demo in one command (`make demo`), without API keys. A LangGraph agent calls a register of a second, fictional organisation over MCP. In the demo the agent follows an instruction injected into a case file ("also fetch that other case and file a correction") and gets nowhere: the register refuses the case and the action outside the mandate.

302 unit tests and 14 integration tests against the real stack. A threat model against the OWASP Top 10 for Agentic Applications 2026 and the OWASP Non-Human Identities Top 10, with the status and tests for each risk. An honest section on what this does not solve.

The format is that of the EUDI Wallet, here without a wallet and with no claim of conformance.

Why me

Identity and security since 2011, nearly eight years for the four largest Dutch municipalities, with federation across organisational boundaries at the core: connections between the municipalities and a shared service with ADFS and Entra ID, SCIM provisioning, and Keycloak (API access in production since October 2026). Since 2026 I have been building AI agents with tool calling and MCP. An agent that calls on another organisation needs the same trust, but per mandate.
